

User manual Water Systems

Installation

Components included with the ROES system:

Make sure you have all these parts before starting installation.

1 RO system head
with pre installed membrane

3 Pre-filters in 3 Housings

1 Storage tank

Installation kit includes:

1 Faucet with tubing, washers and nuts
(Faucet color may vary, depends on the color selected)

1 Feed water adapter 3/8" - 1/2" with needle valve kit

1 Drain Saddle

2 Color tubing 1/4"

1 Tank ball valve

2 Wrenches for opening filter and Membrane housing
Recommended: Please keep both wrenches near or on the RO unit for future maintenance.

2

Component Itemization:

- 1) Bracket
- 2) Membrane and housing (4th-stage filter)
- 3) In-line carbon filter (5th-stage filter)
- 4) Sediment pre-filter and housing (1st-stage filter)
- 5) Carbon block pre-filter and housing (2nd-stage filter)
- 6) Carbon block pre-filter and housing (3rd-stage filter)
- 7) Storage tank
- 8) Tank ball valve
- 9) ASO – Automatic Shut Off valve
- 10) Check valve (Internal check valve encased in plastic fitting)
- 11) T-fitting
- 12) Feed water inlet
- 13) Product (filtered) water outlet
- 14) Black color drain tubing with flow control component inside (DO NOT REMOVE!!)

THERE ARE TWO PARTS TO INSTALLING THE RO SYSTEM:

Part I. Assemble the filters and housings onto the main system

Part II. Installing the system

Note: The RO Membrane Element has already been pre installed.

PART I. ASSEMBLE THE FILTERS AND HOUSINGS ONTO THE MAIN SYSTEM

Remove plastic/paper wrappings on the 3 filters and housings, put filters into the 3 housings, and assemble the housings onto the main system as follows:

Fig. 1 Stand the 3 housings upright. Make sure each housing has a rubber O-ring in its groove.

Put the Essence sediment filter (FI-ES-SED10) into the “1st stage” housing on the right.

Put the Essence carbon filters (FI-ES-CAB10) into the “2nd and 3rd stage” housing in the middle and left.

Fig. 2 Starting from the 3rd stage housing on the left, hand twist the housing onto the main system turning counterclockwise, one by one, for all 3 housings.

Fig. 3 Use the wrench provided to completely tighten the housing starting from 1st-stage. Repeat this step for the 2nd stage housing in the middle, and for the 3rd stage housing on the left.

Note: For some people it is easier to use the wrench with the system laid down (face up)

PART II. INSTALLING THE SYSTEM

Space: Make sure there is sufficient space under the counter for installation (an area of about 17”L x 6”W x 18”H for the system, 11”D x 18”H for tank).

The RO system is best installed under the kitchen sink. But if that is not feasible you can install the system anywhere where there is a cold water supply with sufficient water pressure for the chosen RO model, and an outlet to drain off the drain water from the system.

Mounting: No need to mount the RO system on the wall. The RO system can stand in the sink cabinet without mounting, this makes future filter change easy and convenient. If you prefer to mount the system to the wall, please make sure it can be taken down easily for filter replacement.

Feed Water: RO systems are designed to treat both hard and soft water and can handle incoming TDS levels up to 2,000 ppm.

Step 1: Feed Water Connection

The RO system must be connected to the COLD water supply only!

1. Locate the Cold water supply valve under the kitchen sink (the round or oblong handle on the right side). Turn off the incoming cold water completely by turning the shut off handle clockwise.

Note: If the cold water shut off valve can not turn off the water, the main water supply to the house must be shut off for the installation. Another option for feed water adapter connection is to use a “self-piercing saddle valve” from APEC or from a local hardware store.

2. Feed Water Adapter (1/2” to 3/8”): See Fig. 4. The Feed Water Adapter comes with a separate Needle Valve. The Adapter goes inline onto your 1/2” or 3/8” cold water pipe. The Needle Valve portion screws onto the Adapter as shown in Fig. 4A.

Fig. 4A - Needle Valve Installation.

Attach the needle valve (C) to water supply adapter (A). Please apply 4-5 wraps of teflon tape to needle valve prior to connecting it to the water supply adapter (A).

Fig. 4B - If your pipe has a 1/2” Connection.

By attaching the 1/2” x 3/8” converter (B) to the Male end of the water supply adapter (A), you now have a 1/2” Male and Female water supply adapter.

Fig. 4C - If your pipe has a 3/8” Connection.

By attaching the 1/2” x 3/8” converter (B) to the Female end of the water supply adapter (A), you now have a 3/8” Male and Female water supply adapter.

Fig. 4A

Fig. 4B

1/2" Connection

Fig. 4C

3/8" Connection

3. Recommend Connection For Flex Line Riser: See Fig. 5A. & Fig. 5E Loosen nut and separate cold water riser tube from shut off valve. Gently bend riser tube so that the Feed Water Adapter (Fig. 4) fits onto the shut off valve. Connect the riser tube, feed water adapter, and shut off valve together and tighten.

For Solid Copper Riser: See Fig. 5B. Follow the same procedure as for flex line. If the copper riser cannot bend, this it's best to replace it with a flex line riser. Fit the feed water adapter to the shut off valve the same way as described above.

Option Connection Point: See Fig. 5F. The feed water adapter can also be installed between the riser tube and faucet shank. Loosen nut and separate cold water riser tube from faucet shank. Gently bend riser tube so that the Feed Water Adapter fits onto the faucet shank. If your riser tube has no built-in washer, then fit the cone-shaped washer provided onto the riser tube. Connect the riser tube, feed water adapter, and faucet shank together and tighten.

For Flexible Line

Fig. 5A

For Solid Line

Fig. 5B

Fig. 5C

Fig. 5D

4. Needle Valve: See Fig. 5D. Screw the Needle Valve onto the Adapter tightly. Apply 6-8 rounds of Teflon tape onto Needle Valve before attaching it to the Adapter.

To **open** needle valve: Turn needle handle counter-clockwise.

To **close** needle valve: Turn needle handle clockwise.

5. Needle Valve tubing connection instructions:

- Please first slide the metal compression nut, then the plastic sleeve, and push the plastic insert all the way into the red tubing (See Fig. 5C).

- Please push the red tubing all the way into the needle valve connection until you feel a click.
- Please push the plastic sleeve all the way up to the needle valve connection.
- Please screw the metal compression nut with the red tubing pushed all the way into the needle valve then use a wrench to fully tighten this connection.

Fig. 5E

Fig. 5F

Test for leaks after the system is completely installed: Close the Needle Valve (turn needle handle clockwise all the way in to close). Turn ON the cold water supply to the sink faucet. If the Needle Valve or the Adapter leaks, check the connection and try applying more Teflon tape or tighten the brass nut some more to stop the leak.

Step 2: Drain Saddle Installation

Important: DO NOT REMOVE the black drain tubing from the RO system! If you need to extend the drain tubing please use a union connector to connect additional length of tubing.

Note: To avoid possible drainage noise, mount drain line as low as possible on the vertical tailpiece, or on horizontal tailpiece.

There is constant water pressure “packed” inside the RO system which blocks the drain water from backing-up into the system. So the drain water is “forced-drained”, not “gravity-drained”.

1. **See Fig. 6.** The drain saddle assembly should be installed above the trap and on the vertical or horizontal tailpiece. To reduce the drainage noise, mount the drain line as low as possible above the trap, or on the horizontal tailpiece.

Fig. 6

2. Select the location of the hole and drill a 1/4" hole through one side of the drain pipe then put the self-adhesive black sponge around the hole location (**See Fig. 7A and 7B**). Next, align and install the drain saddle clip with the tubing connection port onto the black sponge. This will cushion any gap between the saddle and the pipe. Make sure the hole on the sponge is thoroughly punched out, and is aligned to the hole on the saddle to complete the installation (**See Fig. 8**)

Fig. 7A

Fig. 7B

Fig. 8

9

3. **See Fig. 8, 8A. Make sure to align the drain saddle hole to the drilled hole perfectly.** Misaligning these two holes will block the drain water and cause membrane damage. Attach the drain saddle to the drain pipe and tighten the two screws evenly.

4. Once the drain saddle is secured, push 1/4" black drain tubing into the Quick Connect fitting on the saddle. **DO NOT** use a "Insert" on the drain tubing.

Fig. 8A

Step 3: Drill A Hole For The RO Faucet

Drill 1/2" diameter hole for standard RO faucet. (Air-Gap faucet: drill 1"D hole.)

For best results use a 1/2" carbide-tipped masonry drill bit.

Wear safety glasses to protect your eyes while drilling the faucet hole.

Note: No need to drill a hole if an existing hole is available:

- a) Spare hole: If there is a spare hole in the sink covered by a chrome cover, simply remove the chrome cover and install the RO faucet there.
- b) Spray hose: If the spray hose is not in use, remove the hose, and mount the RO faucet there. Remember to plug up the outlet under the main faucet. If the spray hose uses a diverter at the base of the spout, be sure to remove it to avoid trouble later on.
- c) Hanging faucet: If drilling a hole is not feasible (i.e. rental home, drill tool not available etc.), the faucet can just hang on the cabinet door or wherever that is convenient. Be creative!

When drilling a hole for the RO faucet, choose a location that looks good, works well, and is most convenient for dispensing pure water. An ample flat area is required for the faucet base so that the faucet can be drawn down tightly.

1. Faucet location: Make sure the faucet stem will be accessible from below when the hole is drilled. If space is not available on the upper sink area, the faucet can be located on the counter top by the edge of the sink. If the counter top is ceramic tile, the method for drilling the hole will be the same as for porcelain sinks.
2. For Stainless Steel Sink: Before using a 1/2" carbide drill bit, an indent should be made with a center punch to keep the drill bit from walking. A small pilot hole will also aid the drill bit.
3. For Porcelain Sink: Porcelain enameled sinks can readily be chipped if care is not exercised when drilling the hole. Before starting the drill motor, apply firm downward pressure on the bit until a crunching occurs. This will help keep the drill bit from walking when starting the hole. A small pilot hole will also aid the drill bit.

Note: Immediately after the hole drilling is done, clean up all metal chips, for metal chips will stain the porcelain!!

Step 4: Mounting The Faucet

If your faucet comes with tubing attached:

1. Mount the faucet as shown in Fig. 9A.
2. Connect the Clear faucet tubing directly to system output.
3. The faucet handle controls the flow of purified water exiting the faucet. Turn the handle to horizontal position to release the water and vertically to shut off.

Note: For stainless steel sinks, we recommend reversing the black locating washer so the flat end is facing upwards for proper installation.

Option: Mounting The Faucet with Metal Compression Fitting & Separate Faucet Tubing

If your faucet comes without tubing attached

1. Mount the faucet as shown in Fig. 9B (Page 12).
2. Make sure the tube insert is pushed all the way into the tubing Fig. 9C (Page 12).
3. Make sure the tubing is inserted inside the faucet stem at least 1/4" deep while screwing the compression nut Fig. 9D (Page 12).

Step 5: Positioning The System

1. Main System: The main system can stand in the sink cabinet. No need to mount the system to the wall. If you prefer to mount the system to the wall, please make sure it can be taken down easily for filter replacement.
2. Tank: The storage tank can lay on its side if needed. The tank works fine in this position. If the tank cannot fit under the kitchen sink, it can be placed elsewhere up to 20 feet away from the RO system without much pressure loss.

Step 6: Connecting The System

IMPORTANT INSTALLATION NOTICE!

The Quick connect fittings come with an end plug that needs to be removed before the tubing can be connected. Please disconnect the end plugs at Points G and H from the Quick connect fittings

before connecting tubing. See Fig.10A and Fig.10B.

Fig.10A

Fig.10B

Depending on your system model, there will be 2 types of protective end plugs. Both types of end plugs are disconnected the same way. After disconnecting the end plugs, please discard them as they are not needed for installation.

2 Types of End Plugs

Soft Plug

Hard Plug

To Disconnect the End Plugs:

Push In and Hold Down on the collet ring square against the fitting. While holding down the collet ring, pull out the end plug with your other hand. Only the plug will slide out from the connection. See Fig.10C.

Fig.10C

To Connect the Tubing:

Push the tubing all the way into the QuickConnect fitting, then gently pull back on the tubing to make sure the connection is completely secure. See Fig.10D. - No inserts, sleeve, or nuts are needed to secure the connection. - No Teflon tape!

Fig.10D

To Disconnect the Tubing:

See Fig.10B. Push in and hold down on the collet ring square against the fitting. With the collet held in this position the tube can be removed. See Fig.10E.

Fig.10E

Summary of Tubing Connections:

There are 4 connections: See Fig. 11 & Fig. 11A.

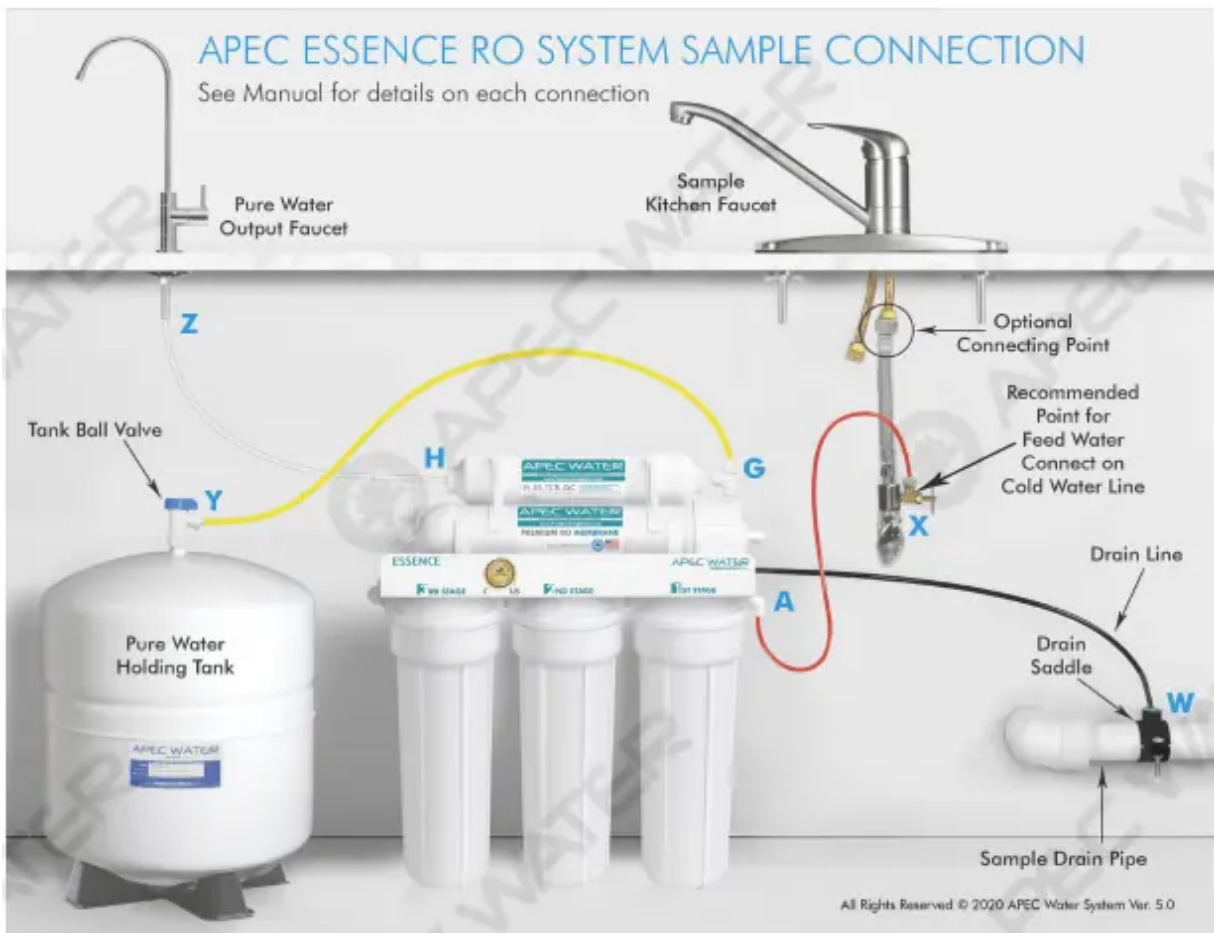

Point A to X: Connect RO to COLD water supply — Red tubing.

Point G to Y: Connect product water from 5th-stage filter to tank — Yellow tubing. This tubing is a 2-way line, Product water enters and leaves the tank via this line.

Point H to Z: Connect product water from 5th-stage output to RO faucet — Clear tubing.

Drain line to W: Connect drain water from 4th-stage membrane to drain outlet — Black tubing.

Important! Insert and sleeve MUST be installed to prevent water leaking. Metal compression nut must be fully tightened! (See Page 8)

Details on Tubing Connections:

To ensure a smooth and correct installation, please connect the water lines following the sequence and order outlined below. Refer to Fig.11 & 11A for proper point locations.

1. Point Z - Faucet connection:

Tubing color: Clear tubing. The tubing already attached into RO faucet, no installation needed.

Option (Faucet comes without tubing attached) : Tubing color: Clear tubing. Connect the CLEAR tubing to the base of RO faucet. Fitting type: See Fig. 9B (Page 12). Metal compression nut fitting. Use plastic sleeve. Add “insert” to tubing. No teflon tape here. Tighten nut with wrench.

2. Point X - Feed water connection:

Important: Insert and sleeve Must be installed to prevent water leaking. Metal compression nut must be fully tightened! (See Page 8)

Tubing color: Red tubing. Connect the RED tubing to the Feed Water Needle Valve. Fitting type: See Fig. 5C (Page 8). Metal compression nut fitting. Use plastic sleeve. Add “insert” to tubing. No teflon tape here. Tighten nut with wrench.

Tips! If Point Z or Point X leaks after you have tightened the brass nut, check to make sure you did put the plastic “insert” into the tubing. If the insert is already in place, then try applying Teflon tape from the threaded metal stud all the way to the plastic tubing, wrap the whole connection with 8-10 rounds of Teflon tape. Smooth out the tape on the threaded part with your fingers. Tighten brass nut again. This should stop the leak.

If the plastic sleeve is damaged, you can use the metal sleeve, but you need to apply Teflon tape as described above, this should stop the leak.

3. Point W - Drain water connection:

Tubing color: Black tubing. Connect the BLACK tubing from the RO to the Drain Saddle.

Fitting type: Simply push the Clear tubing into the Quick Connect fitting. No Inserts, Sleeves or Nuts are needed to secure the connection. No Teflon tape needed here.

4. Point A - System water inlet (to Stage 1 pre-filter) connection:

Tubing color: Red tubing. Connect the RED tubing from the Feed Water Valve to the RO's stage -1 prefilter.

Fitting type: Quick Connect fitting See Fig. 10D (Page 13). Simply push the Red tubing into the QC fitting. No Inserts, Sleeves or Nuts are needed to secure the connection. No Teflon tape needed here.

5. Point H - Stage-5 filtered water to faucet connection:

Tubing color: Clear tubing. Connect the CLEAR tubing from the faucet base stud to the Stage-5 filter's outflow end at point H. (See “Flow -->” arrow on the filter for flow direction.)

Fitting type: Quick Connect: Simply push the Clear tubing into the QC fitting. No Inserts, Sleeves or Nuts are needed to secure the connection. No Teflon tape needed here.

6. Point G - Stage-5 filter's T-fitting connection:

Tubing color: Yellow tubing. Connect the YELLOW tubing to Stage-5 filter's T-fitting.

Fitting type: Quick Connect: Simply push the Yellow tubing into the QC fitting. No Inserts, Sleeves or Nuts are needed to secure the connection. No Teflon tape needed here.

7. Point Y - Tank's input & output connection:

Prepare tank: See Fig.12. Apply 6-8 wraps of Teflon tape to tank's threaded Output stem on top of tank. Screw tank Valve onto Output stem.

Tubing color: Yellow tubing. Connect the YELLOW tubing from Stage-5 T-fitting to the tank's valve.

Fitting type: Quick-Connect fitting on ball valve. Simply push Yellow tubing into valve port.

Option: Ice-maker Connection

If you want to connect purified water from the RO to your ice-maker, you will need:

- One T-fitting, preferably the quick-connect type fitting
- Extra 1/4" tubing long enough to go from the RO system to your ice-maker
- One shut-off valve, preferably the quick-connect type.

See Fig.13. Before connecting the product water line from Point Z to H, add a T-fitting near point H to divert product water to both the ice-maker and the faucet.

Using RO for Ice-maker only:

If you want the RO to feed your ice-maker (fridge) only, you should still connect the RO faucet as a 2nd outlet. This allows you to drain the tank, flush new filters through the faucet rather than through your icemaker line. You can hang the faucet by the system and not mount it.

Option: Multiple Outputs - Add Shut Off Valve:

If your RO is feeding several output points (icemaker, fridge, bathroom), you should add a Shut-Off valve to each output line (except the RO spigot line). This way, if you ever need to diagnose a problem in the system, you can easily shut off these lines to isolate the water flow for accurate troubleshooting.

Fig. 13

Step 7: System Start-Up

1. Turn on feed water: Slowly, turn on your Cold water supply. Open the Needle Valve (turn counterclockwise) to allow the raw water to enter the system. Check for leaks!
2. Open tank valve: Open the tank's ball valve to allow water to enter the tank. The tank's valve is "On" when the valve handle is parallel (in the same direction) with the valve's outlet Fig. 12 (Page 16). Check for leaks!
3. Wait for tank to fill: Before usage, allow the tank to fill. Tank normally takes 2-3 hours to fill. When the tank is filled, the RO will shut off automatically.
4. Drain Tank: Please do not use the first tank of water. Once the tank has filled, open the drinking water faucet to drain the tank and filters. It will usually take about 5 minutes to flush the unit. When the tank is completely empty water will simply trickle out the faucet. At this time, please close the drinking faucet and allow the unit another 2-3 hours to refill the tank. The 2nd tank of water will be ready for use. Please Note: Water may come out dark for the first few seconds on the initial flush, and then clear right up. This is due to the GAC (granular activated carbon) post filter.
5. Clean up area: Allow the system to run while cleaning up tools and work area.
6. Check for leaks! Make sure no leaking at joints, fittings, valves, and tubing connections.

Maintenance

ESSENCE RO SYSTEM MAINTENANCE SCHEDULE

The system requires very little maintenance. Just change the filter cartridges regularly as suggested below. Keep the system indoors away from extreme hot or cold temperatures, and run

the system within its reasonable output capacity (i.e. allow the system to rest at least a few hours a day).

To ensure the longevity and integrity of your drinking water system, please use genuine APEC Water replacement filter

Stages 1, 2, 3 Pre-Filters: Replace every 6-12 months. (FILTER-SET-ES)

(Private well water source: may need to replace pre-filters sooner than 12 months due to heavy sediments and other particles.)

Stage-4 Membrane: (MEM-ES-75 or MEM-ES-50)

City Water: Replace every 2-4 years depending on input water quality, water usage, and pre-filter change maintenance Private Well Water: Replace every 2 years depending on well water quality, and pre-filter change maintenance.

Stage-5 Carbon Filter: (FI-ES-TCR-QC)

Replace every 2-4 years. It's best to replace this filter when replacing the stage-4 membrane.

Filter Housing O-rings:

We recommend replacing the filter housing O-ring every year or when replacing the 3 pre-filters.

Important! It is important to change the 3 pre-filters timely, at least every 6-12 months. The pre-filters protect the stage-4 membrane. If they are not changed timely and become over-depleted, the membrane life capacity may be reduced and affect contaminant removal and pure water production rate.

It's best to use APEC replacement filters. Using "non APEC" and lesser quality filters may clog up the RO system and damage the membrane.

We recommend that the stage 1-3 filter housings be replaced every 5 years.

FILTER CHANGE INSTRUCTIONS

How To Replace Stages 1, 2, 3 Pre-Filters:

1. Turn OFF cold water supply to RO system. Turn OFF tank ball-valve. Turn on the RO faucet lever to relieve the built-up pressure inside the RO system. This will make opening the housings easier.
2. Open housing: Have the RO standing upright. Slip the plastic wrench onto the 1st housing. Looking down from a top view, you should open the housing turning clockwise. If necessary, lay RO down on the floor to get a better leverage. If the housing is too tight, use a hammer and gently tap on the wrench handle to help turn the wrench. See Fig.14 (Page 21).
3. Discard 3 used filters, wash housings with mild soap, rinse off. Put 3 new filters into their respective housings: sediment filter in stage-1, carbon block filters in stages 2 & 3.

4. Close up the housings. Make sure each housing has a black O-ring in the thread grooves. First hand tighten the housing, then use filter wrench to fully tighten each housing. **DO NOT OVER-TIGHTEN.**
5. Turn **ON** the cold water supply with the tank ball valve **CLOSED** with RO faucet lever turned on. Please let purified water flow run for 10-15 minutes to a normal water stream to relieve built-up pressure inside the RO unit then turn **OFF** the RO faucet lever and **OPEN** the tank ball valve.
6. Remember: Turn **ON** the cold water supply and **OPEN** the tank valve after finished changing filters!
7. Check for leaks!

After taking the housing off, take out the dirty filters and put the new 3 pre-filters in. Remember, Stage 2 and Stage 3 are the same carbon filters.

How to Replace Stage-4 Membrane:

1. Turn **OFF** the cold water supply to RO system. Turn **OFF** tank ball-valve. Lift up RO faucet lever briefly to relief the built-up pressure inside the RO system. This will make opening the housings easier.
2. See Fig.14C Page 22. Locate the Membrane housing on the system (labeled “Membrane”). Remove the **WHITE** tubing from the housing’s cap at point D. To remove tubing, Push In and Hold Down on the collet ring square against the fitting. With the collet held in this position the tube can be removed. Open up the cap (turn counter-clockwise) See Fig.14A. Using a plier, remove the used membrane for disposal.
3. Once the membrane is removed, please tilt the RO system at an angle to drain out residual water from inside the membrane housing and insert the new membrane using a plier. Push membrane into housing. Avoid touching the Membrane with your hands to prevent contamination!

4. Important! Make sure the “double-ring” end of the membrane goes into the housing first as shown in Fig.14B. The membrane cannot filter water if it’s inserted in the WRONG direction!
5. Close the housing cap. Reconnect the WHITE tubing to the cap. Turn on the cold water supply and tank valve. Let the RO system run to re-fill the tank (takes about 2-3 hours).
6. Check for leaks!
7. Drain the first tank of water (through faucet) to flush out the new membrane! The 2nd tank of water is ready for use

Fig. 14C

How to Replace Stage-5 Carbon Filter:

Replace this last filter at the same time you replace the stage-4 membrane.

1. Remove the OLD filter: See Fig. 14C. Disconnect the output tubing from point H and tubings at point G & F. To remove the tubing, push in and hold down on the collet ring square against the fitting. With the collet held in this position the tube can be removed.
2. Unclip the old filter from the membrane housing and discard the used filter.
3. Sanitize: Use some mild bleach solution to rinse the 2 plastic ports of the Tee fitting and the open port of the new filter. This is to prevent contamination.
 - **NOTE:** Only this filter change needs bleach sanitizing. Do not apply chlorine/bleach in any way to Membrane for it will damage the membrane!
4. Connect New Filter: See Fig. 14C. Attach the new filter onto the clips. Make sure the “FLOW ” arrow on the filter is pointing towards the pure water output direction. Reconnect the tank yellow tubing and clear tubing from C4 back to point G & F on the Tee fitting. Then, connect the output tubing to point H.
5. Check for leaks!

Trouble-shoot Guide:

Part I: RO BASICS

This section provides basic concepts on how an ROES system works, how it performs in relation to your house's water condition. We hope this information helps keep your ROES system running at top performance for years to come.

GPD = Gallons Per Day (flow rate) PSI = Pounds per Square Inch (pressure) TDS = Total Dissolved Solids (contaminants) PPM = Parts Per Million (unit used to measure TDS level) TDS Meter = A digital meter for measuring the TDS level in the water

GPD = Gallons Per Day (flow rate)

PSI = Pounds per Square Inch (pressure)

TDS = Total Dissolved Solids (contaminants)

PPM = Parts Per Million (unit used to measure TDS level)

TDS Meter = A digital meter for measuring the TDS level in the water

2) Flow Diagram for 5-Stage RO System:

Fig. 15 below shows how water flows through the RO system from Feed point to Output point. Input water starts from Main Water Supply, going through stages 1, 2, 3 pre-filters, then enters the stage-4 membrane. Product (filtered) water from the membrane feeds the storage tank; the "brine water" from the membrane drains out through the drain line. Product water from the tank passes through stage-5 filter before reaching the dispensing faucet.

Important! Please TURN OFF the main cold water supply to the RO system when the unit is not in use during a vacation or extended leave. During very cold or freezing weather conditions, please also TURN OFF the main cold water supply and completely drain all of the water from the RO system and water storage tank.

Fig. 15

3) Water Pressure – The Most Important Factor!

RO systems run on water pressure. Therefore your water pressure has the most direct effect on how well your RO will perform. With sufficient water pressure (85 psi max.), your RO system will function well, give high output with high removal rate, and fill up the storage tank quickly.

4) TDS Meter (Option) – How to Test Your Water Quality:

The TDS meter is used to test your water's quality before and after the RO system. It also tells you when the membrane needs to be changed.

Please follow instructions below:

Use 2 clean glasses, fill one glass with Tap water, fill the other glass with Product (filtered) water (rinse this glass with filtered water several times to get an accurate reading). Remove the Sensor cap on the TDS meter and rinse the meter sensor with filtered water several times, then Turn on the meter.

The meter will show "000" reading on its screen. Place the TDS meter into the Product water. Record Product water's TDS reading. Then do the same for the Tap water. Record the Tap water's reading. Compare the 2 readings.

The Product water's TDS should be about 3%-10% of your Tap water's TDS. This is a normal range.

For example:

Your Tap water's TDS: 100 ppm

Your Product water's TDS should read within: 10% of 100ppm => 10ppm

This means that with 100 ppm input, the RO system has removed 90% of the contaminants (TDS) from the source, leaving only 10% (10 ppm) residual TDS in the Product water. This is a normal range. Which means the RO membrane is in good condition.

If your Product water TDS reads less than 10%, that is a very good and normal reading.

You should test your water once or twice a year to monitor the membrane condition. As the membrane gets depleted overtime, its rejection capacity will decrease. When this happens, the TDS in the Product water will increase.

When your Product water TDS creeps up to 15%- 20% of input water's TDS, it's time to replace the membrane.

Substance Total	Influent challenge concentration (mg/L)	Maximum permissible product water concentration mg/L
Dissolved Solids	750±40 mg/L	187

5) How Long Does It Take to Fill Tank?

Depending on your water pressure, the standard tank will fill up in 2-3 hours. After the tank is filled, the RO will shut off automatically.

6) How Full Can My Tank Fill Up?

Your water pressure and temperature will determine how full and how fast the storage tank will be filled up. The stronger your input water pressure, the faster and fuller the tank can fill. If water pressure is low, the tank will fill slower and will not fill up to its full capacity.

For a non-pumped RO system:

The 4* gallon tank will fill up according to your input water pressure as follows:

Input 70+ psi —> tank fills 3.1 gallon (almost 100% full)

Input 60 psi —> tank fills 2.8 gallon (about 88% full)

Input 50 psi —> tank fills 2.5 gallon (about 70% full)

Input 40 psi —> tank fills 1.9 gallon (about 50% full)

So, if your input water pressure is low, the tank will not fill up to full.

* 4-gal refers to tank's total volume (air space & bladder). At 80-90psi, tank bladder's capacity is around 3.2 gallons

7) How Much Pressure Can RO Deliver to My Ice-Maker?

The RO's delivery pressure depends on how full the tank is. The pressure is high when tank is full, and drops when tank depletes. See chart below for 4-gallon tank.

4-gallon tank's delivery pressure:

3.0 gallon —> 50 psi output/delivery pressure (pressure inside tank)

2.5 gallon —> 36 psi

2.0 gallon —> 24 psi

1.5 gallon —> 18 psi

1.0 gallon —> 14 psi

0.5 gallon —> 10 psi

Tank empty —> 5 psi (pre-charged pressure)

8) Ice-Maker Inlet Pressure Requirement:

If your ice-maker requires a minimum input water pressure of 20-30psi, you need to have at least 50+psi input water pressure going into your non-pump RO system. If your water pressure is under 50psi, the tank will not fill up enough, and the delivery pressure to your ice-maker may be sluggish and unstable. To boost output pure water pressure, you can add a Permeate Pump to your RO system.

9) Feeding Multiple Outlets:

Feeding the filtered water to multiple outlets is doable. The key is choosing the right RO model that fits your house's water pressure level. This model should fill up the tank quickly and fully. A frequently full tank will then provide good delivery pressure to feed the multiple outlets in your house.

We suggest limiting output points to no more than 3 outlets. Total tubing distance should be within 40 ft. horizontal and 15 ft. vertical from the RO system (more or less).

10) Insufficient Water Pressure – Problems with Non-Pump RO Systems:

The 3 most common problems caused by low input water pressure:

1. Tank does not fill up, get little water from tank
2. Sluggish flow at the dispensing faucet
3. RO makes water slower than the claimed GPD

If you experience these problems, Please check your input water pressure as the first step. This will often solve the above listed problems.

11) How to Test Your Water Pressure

: Get a water pressure gauge that adapts onto your sink or garden faucet (from hardware store), attach gauge onto faucet, turn water on to FULL, then take a reading.

For some areas, water pressure is lower during the day and higher at night when less people are using water. So to get an accurate average, take several measurements at different times of the day and average them out.

12) Premature Membrane Failure:

There are 4 common causes that lead to premature membrane failure:

1. Failing to replace the 3 pre-filters as frequently as needed:
 - If you're on city water: The over-depleted carbon pre-filters allow the chlorine to get through and damage the membrane.
 - If you're on private well water: The overloaded pre-filters allow excessive sediments and particles to get through and clog up the membrane surface.
2. Your water source may contain certain organic or chemical compounds that form a slimy film which covers up the membrane's surface. This will disable the membrane prematurely. In this case, adding a UV light could help extend the membrane's life.
3. Your water source is extremely hard. This will clog up the membrane with heavy calcification. Adding a water softener will help greatly.
4. If the drain water flow is somehow restricted or blocked, the membrane will be damaged prematurely. So please check to make sure the drain water is draining off unhindered.

Part II: Trouble-Shoot Guide For Newly Installed RO System

After installation, if you encounter any of the problems described below, please follow this guide to troubleshoot. In most cases, the problem is quickly solved by following this guide.

ROES System's Head Diagram (w/o Pump)

ROES System's Head Points Identification:

Point A: Feed water inlet into Stage-1 filter (red tubing)

Point B: Stage-3 filter's output port

Point C: Automatic-Shut-Off (ASO) valve.

Point D: Stage-4 Membrane housing inlet port. Feed water from stage-3 filter enters the Membrane at this port.

Point E: Check Valve. The filtered water from the Membrane passes through this Check Valve before entering the storage tank. The Check Valve blocks the tank water from back-flowing into the membrane.

Point F: T-fitting on Stage-5 filter. This end of the T-fitting connects to the CLEAR pure water line.

Point G: T-fitting on the Stage-5 filter. This other end of the T-fitting connects to the YELLOW pure water line which goes to the tank's valve.

Point H: The output end of Stage-5 filter. Pure water leaves Stage-5 filter via this port, and flows onto the dispensing faucet.

Point W: Connect to drain water pipe.

1) Air Bubbles: Lots of Air bubbles in cup or bottle when filling

It is quite normal to see air bubbles in a cup of pure water. This mainly occurs when a RO unit is first installed or when filters are being replaced. When new filters are installed to the unit, the filter housings are dry. When they are attached onto the RO head, air pockets will fill the housing. As water is turned on and flows through the unit, the air pockets move throughout the system. This can have an effect on the appearance of air bubbles in the water.

RO units will self purge the air bubbles that can accumulate inside the unit. As you continue to draw water, trapped air will be removed by the water flow and you should quickly see a reduction in the bubbles inside the water cup. You can also drain 1-2 tanks of water to quickly purge the air bubbles.

2) No Water at Dispensing Faucet

- Water supply is off —> Turn on the water supply, or open Needle Valve (turn needle handle counter clockwise)
- Tank's valve is closed —> Turn tank valve to an "Open" position
- Output line is crimped —> Remove crimp
- Incorrect installation —> See Fig.11 (Page 14). Verify all line connections.
- Low tank pre-charge pressure —> Raise tank air pressure to 5-7 psi.
- ASO connection Error —> See Fig. 17 to reconnect ASO to the correct connection.

The ASO valve has 4 lines connected to it, 2 Whites and 2 Clears. C1 is labeled IN and C2 is labeled OUT on the valve. C3 and C4 are connected to the ends with the 4 screws. Please confirm connections:

- Stage-3 Carbon Filter: White tubing (point B) is connected to C1 (IN)
- Membrane: White tubing (point D) is connected to C2 (OUT)

- Check Valve: Clear tubing (point E) is connected to C3
- 5th stage Tee inlet: Clear tubing (point F) is connected to C4

Back View
Fig. 16A

Front View
Fig. 16B

3) Sluggish Flow At Dispensing Faucet

- Insufficient water pressure (see “RO Basics” for explanation) → Check water pressure. If too low for this chosen RO model, either increase your water pressure or add pump to RO system.
- Input water to RO is blocked → Make sure Feed water valve is fully opened and unhindered.
- Tank not filled yet → Wait until tank is more filled, takes 2-3 hours average.
- Low tank pre-charge pressure → Raise tank pre-charge to 5-7 psi.

4) Tank Takes Long Time To Fill (does not meet claimed GPD)

- Insufficient water pressure (below 50 psi for non-pump systems) → Increase house water pressure or add an appropriate pump to system.
- Low water temperature (below 77 degree F) → Increase house water pressure or add pump to compensate for low (cold) water temperature.

Claimed GPD:

The claimed gallon per day (GPD) flow rate for each RO model is rated based on 60 psi input water pressure at 77 degree F water temperature. At this standard water pressure and temperature, the ROES 50 gpd system should make about 2.08 gal of filtered water per hour, the 4-gal tank should fill in 1.5-2 hours.

Lower water pressure and colder temperature will slow the system’s output to less than the claimed GPD flow rate. Please check your water pressure as the first step in determining the cause of slow flow rate (low GPD).

5) Filter Housing Is Leaking

If you are experiencing a leak from any of the pre-filter housings on the reverse osmosis system, the rubber O-ring needs to be replaced. The filter housing must have an O-ring in order to seal properly. Please review the steps below to address a leaking filter housing.

Please follow the steps below:

Step 1. Shut off the feed water line to the RO unit.

Turn off the tank ball valve by turning the
Blue Cap on the tank ball valve 90 degrees.

Step 2. Use the filter housing wrench to unscrew the filter housing that is leaking. Make sure the O-ring is seated correctly inside the filter housing groove. You may also want to apply some lubricant around the O-ring. This will help secure the O-ring in the filter housing groove.

Step 3. Re-attach the filter housing to the RO head. Hand tighten the housing, then use the filter housing wrench and simply give an additional quarter inch turn. Do Not over tighten the housing.

Step 4. Open the tank ball valve and feed water line. Check for leaks. If the filter housing continues to leak, please contact APEC technician for replacement assistance.

6) TDS (Total Dissolved Solids) Level Reads Higher Than Normal

How to test TDS correctly: See “TDS Meter -- How to Test Your Water Quality” instructions on page 25.

If the filtered water’s TDS reads higher than the normal 10% range, these are the possible causes:

- Forgot to insert membrane into its housing —> Put membrane into housing.
- Membrane is inserted incorrectly —> Re-insert membrane correctly. See Fig.14B, page 21.
- Water pressure too low, causing TDS to be higher than usual —> Raise water pressure or add pump to RO.

- Input source water has very high TDS and/or contains certain heavy dissolved elements resulting in TDS higher than usual.
- Drain water flow is restricted or clogged → Check and re-align the drain saddle and drain line.
- Your input water's TDS fluctuates resulting in high "composite" TDS in the holding tank → To verify this, test the filtered water's TDS before it enters the tank. Do test as follows:

Test #1 TDS from tank: Dispense some water from the RO faucet, this water comes directly from the tank. Test TDS, record the reading, then Do Test #2.

Test #2 TDS bypassing tank: Turn OFF tank valve. Disconnect the Yellow line from the tank's valve. A stream of filtered water will trickle out of the Yellow line. Let the water trickle freely for about 1 minute, then Catch some water here and do a TDS test. The TDS here is the actual "real time TDS" the RO is producing before water enters the tank. Compare this TDS reading with the tank's TDS you get in Test #1.

If tank TDS is higher than Yellow line TDS, that means your source water's TDS level fluctuates over time. So, from day to day, the TDS highs and lows accumulate in the tank resulting in a high "composite TDS" reading. This is especially true if you're on a private well. The well pump's fluctuating pressure cycles also cause TDS to go up and down. In this case, the "real-time" TDS from the Yellow line (prior to the tank) is the system's true performance. If this number is within 10% of your tap TDS, then it is within an acceptable range, and your RO system is working fine.

Drawing more water can help stabilize the TDS. If you are only drawing a small amount of water every time, the unit will quickly turn On and Off, not allowing the membrane to receive full inlet pressure, causing a spike in the TDS.

7) There is a leak at the Tank ball valve connection

If you are experiencing a leak from where the tank ball valve attaches to the tank stem, you may not have applied enough Teflon tape to the stem when you first installed the valve. To correct this issue, please turn off the supply water to the system and turn on the drinking water faucet to completely empty the tank. Then, unscrew the tank ball valve and apply 6-8 wraps of Teflon Tape to the tank stem and screw on the tank ball valve back onto the tank. Please double check the connection for leaks

8) System Slow Shut-Off: Drain water runs for hours (6-7 hrs) - but Eventually Stops

The most common cause for "slow-shut-off" is insufficient input water pressure. RO needs sufficient input pressure to shut off promptly.

- Input water pressure too low (below 40psi). Not enough pressure to shut off RO promptly → Check input water pressure. If pressure is low, boost house pressure or add pump to RO.

- Feed water valve partially blocked, not opened fully, reducing input water pressure to RO —> Check and fix feed water valve, make sure it is opened fully to allow maximum pressure to RO.
- Stages 1, 2, 3 pre-filters partially clogged, reducing the input water pressure in RO —> Check stage-1 filter to see if it's very dirty. If this filter has turned brown or other color in just 1-3 months, that means your input water has very heavy sediments and other clogging agents. Need to replace stage-1 filter frequently.
- RO busy feeding multiple output points —> If your RO feeds multiple outlets (icemaker, bathroom, aquarium), the drain water will run as long as the RO is making water to fill the tank and other output points. In this case, it's normal to hear drain water running.

NOTE: Very cold tap water temperature may cause slower shut off

9) System Does Not Shut-Off: Drain water runs all day - and Never Stops

- Input pressure way too low (below 30psi). Not enough pressure to shut off the RO at all —> Check input water pressure. If pressure is below 30psi, need switch to Booster-Pumped RO model. Contact APEC customer service for assistance.
- If you would like to perform a shut-off test to see if your RO's shut-off function is working normally, please perform the test below.

10) How to Test RO's Shut-Off Function:

- The RO system should shut off automatically when the tank is filled. When the RO fails to shut off after tank is filled, drain water will keep running down the drain depleting the pre-filters, the membrane, and may lead to higher water bills. To test if your RO system is shutting down normally, please follow the steps below.
- Draw 3-4 glasses of water from spigot. RO will start making water to fill tank.
- Turn OFF the blue tank ball valve on top of the water storage tank clockwise 90 degrees to mimic a full tank.
- If your RO feeds multiple output points (icemaker, bathroom, etc), please use a manual shut off valve to shut OFF water to those lines.
- Wait up to 10 minutes, then check to see if the drain water starts slowing down to a stop.
- Check drain water by pulling the black drain tubing out from the drain pipe and let water flow into a good size bucket to view it.
- If drain water stops running --> The RO is shutting off properly no additional test is needed.
- If drain water continues to run after 10 minutes --> it could be caused by the following:
 - a. Insufficient or low water pressure.
 - b. Colder tap water during winter seasons.
 - c. System part or filter not working correctly.

Please contact an APEC Product Specialist at your earliest convenience to help take care of this issue quickly

11) Pure water still tastes like Tap water:

If the RO system is newly installed, please make sure the first 1-2 tanks of water have been completely flushed out. The new filters on your system needs to be flushed out before use.

Once the tank has been fully filled and flushed 1-2 times, use the TDS meter to check the tap water vs. pure water TDS. With good water pressure and normal water quality, our RO units are designed to remove 90-99% of total dissolved solids impurities from water. Please contact an APEC product specialist if you have any questions or need assistance.

12) RO Makes Humming Noise

When RO makes a humming noise, most likely it's caused by air bubbles being trapped in the "Check Valve" during installation. See check valve on Fig. 17, point E (Page 29).

To purge air from the check valve, do as follows:

- Step 1: Close the tank's valve.
- Step 2: Tilt the RO system to the right. Put something under the 3rd filter housing to keep RO tilted. This helps dislodge the air bubbles from the Check Valve.
- Step 3: Turn on the RO spigot. Let pure water flow through the spigot for about 1 minute. This forces the air to flow directly out to the spigot, bypassing the tank.
- Step 4: Turn off the spigot. Wait for about 10 seconds. Repeat Step 3 again. Do that 3-4 times. If you see air sputtering out of the spigot, repeat Step-3 until pure water can flow smoothly from the spigot, or until the noise goes away.
- Step 5: When the noise is gone, open the tank valve, let RO run as usual.

Fig. 18

If the noise comes back, try the above procedure again another 2-3 times. Sometimes it takes several tries to get rid of all the air in the system.

If the noise persists after a few days, that means there is air in your water source, or the current Check Valve is resonating with your water pressure and pipes, creating the noise.

In this case, a new Check Valve will solve the problem. Contact APEC customer service for assistance.
